1. Essential Command Reference Journal

Below is the structured list of all core Git version control commands executed during the initialization, staging, committing, remote configuration, and remote deployment of the local repository.

Command Executed	Scope / Target	Technical Function & Purpose
<code>git init</code>	Local Folder	Initializes a new empty Git tracking repository inside the working directory, creating the hidden <code>.git</code> database folder.
<code>git config user.name</code>	Global / Local	Sets the author identity name associated with every commit snapshot saved in the repository history.
<code>git config user.email</code>	Global / Local	Sets the author email address linked to the GitHub account for commit attribution.
<code>git add .</code>	Staging Area	Adds all current working directory files (new, edited, or modified) into the temporary staging area.
<code>git commit -m "..."</code>	Local Repository	Captures a permanent historical snapshot of staged files accompanied by a descriptive log message.
<code>git branch -M main</code>	Branching	Renames the initial local default branch from <code>master</code> to <code>main</code> to match standard modern GitHub conventions.

<code>git remote add origin</code>	Remote Link	Links the local repository to the remote web destination hosted on GitHub under the shorthand nickname origin.
<code>git push -u origin main</code>	Remote Deployment	Uploads local main branch commits to GitHub and sets upstream tracking for future single-word <code>git push</code> commands.

2. Execution Terminal History Log

Verification sequence transcribed directly from the VS Code PowerShell terminal session

```
PS C:\it0043-portfolio> git init
Initialized empty Git repository in C:/it0043-portfolio/.git/

PS C:\it0043-portfolio> git add .
```
